Treatment-Resistant Depression (TRD)

Maurizio Fava, MD

Director, Division of Clinical Research of the MGH Research Institute
Executive Vice Chair, MGH Department of Psychiatry
Executive Director, MGH Clinical Trials Network and Institute (CTNI)

Associate Dean for Clinical and Translational Research
Slater Family Professor of Psychiatry, Harvard Medical School
First Steps in the Evaluation of TRD Patients

- Diagnostic reassessment
  - Is the patient unipolar or bipolar?
  - What are the psychiatric and medical comorbidities?
- Were the previous trials adequate in dose and duration?
- Are the blood levels of the antidepressant in a therapeutic range?
- What are the possible contributing factors?
Contributing Factors to TRD

- Misdiagnosis (e.g., bipolar disorder)
- Psychiatric comorbidity (e.g., substance abuse, OCD, PTSD)
- Medical comorbidity (e.g., hypothyroidism)
- Psychotic features
- Pharmacokinetic factors
  - Concomitant use of metabolic inducers
  - Rapid/fast metabolizers
Treatment Strategies for TRD

- Switching
- Dose Increase
- Augmentation
- Combination
Switching Treatments: For Whom?

Non-Response

Partial Response

Marked Intolerance

Switching
Switches: Rationales

• Switch within Class:
  – There may be some differences across agents within the same class in pharmacological properties in vitro or in vivo (e.g., relatively greater uptake inhibition of other neurotransmitters such as norepinephrine or dopamine)

• Switch to a Different Class:
  – To obtain a different neurochemical effect (e.g., from a relatively serotonergic agent to a relatively noradrenergic agent)
  – A specific depressive subtype may be more responsive to one antidepressant class than another
Percent of Remission in STAR*D L-2 Switch

Percent of Remission in STAR*D L-3 Switch

- HRSD-17:
  - MRT (n = 114): 12.3%
  - NTP (n = 121): 19.8%

- QIDS-SR-16:
  - MRT (n = 114): 8.0%
  - NTP (n = 121): 12.4%

Switching: Practical Approaches

• Gradual tapering the first agent while starting the new one
  – Side effects of the new drug may be intensified by the concurrent presence of the first agent
  – “Start low and go slow” with the new agent
  – Consider possible drug-drug interactions
• Abrupt replacement with within class-switches
• Wash-outs are necessary with MAOIs (either when you start them or when you stop them)
Dose Increase

• Definition:
  − The use of doses higher than those considered standard for a given antidepressant

• Rationale:
  − To increase the chance of obtaining adequate blood levels in rapid metabolizers
  − To obtain a different neurochemical effect (e.g., going from a relatively selective serotonergic effect at lower doses to a dual-action effect at higher doses)
Double-Blind Study of High-Dose Fluoxetine vs. Lithium or Desipramine: Augmentation of Fluoxetine in Partial & Non-Responders to Fluoxetine

Trial Design

MDD patients resistant to 8 weeks of fluoxetine 20 mg/day

High-dose fluoxetine (40-60 mg/day)

Fluoxetine 20 mg/day + Desipramine 25-50 mg/day

Fluoxetine 20 mg/day + Lithium 300-600 mg/day

Double-Blind Studies of High-Dose Fluoxetine vs. Fluoxetine Augmentation with Lithium or Desipramine (n = 142)

Dose Increase: Practical Approaches

- Gradual increasing the dose by 50-100%
- Wait at least 4 weeks before deciding whether this strategy helps
- If no side effects are present, consider increasing the dose further
- Blood levels may be informative (even with SSRIs or other newer antidepressants)
Augmentation

• Definition: the use of a psychotropic agent (without per se an indication for depression) to enhance the effect of an antidepressant

• Rationale:
  – To obtain a different neurochemical effect by adding an agent affecting different neurotransmitter systems
  – To broaden the therapeutic effect (e.g., by adding an anti-anxiety agent to an antidepressant)
  – To combine agents with different mechanisms of action and/or indications
Lithium Augmentation

• Lithium augmentation (> 600 mg/day) of TCAs, MAOIs, and SSRIs (Bauer M, Dopfmer S. J Clin Psychopharmacol. 1999 Oct;19(5):427-34.)

• Disadvantages:
  - Need for blood monitoring

• Advantage: The pooled odds ratio (from 9 studies) of response during lithium augmentation compared with placebo is 3.31 (95% confidence interval: 1.46-7.53) (Bauer M, Dopfmer S. J Clin Psychopharmacol. 1999 Oct;19(5):427-34.)
Meta-Analysis of Lithium Augmentation of Tricyclic and Second Generation Antidepressants in MDD

Fig. 2. Meta-analysis of 9 randomized placebo-controlled lithium augmentation trials in depression with 10 contrasts grouped by the type of antidepressant augmented.

Double-Blind, Placebo-Controlled Study of Lithium Augmentation of Nortriptyline

Thyroid Augmentation

• Thyroid hormone augmentation (25-50 mcg/day) (Aronson R et al. Arch Gen Psychiatry. 1996 Sep;53(9):842-8.)

• L-triiodothyronine (T3) has been used in preference and has been thought to be superior to thyroxine (T4) (Joffe RT, Singer W. Psychiatry Res. 1990 Jun;32(3):241-51.)

• Disadvantages:

• Advantage: Among the four randomized, double-blind studies, pooled effects were not significant (relative response: 1.53; 95% CI: 0.70-3.35; \( p = .29 \)) (Aronson R et al. Arch Gen Psychiatry. 1996 Sep;53(9):842-8.)
Percent of Remission in STAR*D L-3 Augmentation

- **HRSD-17**
  - Lithium: 15.9%
  - T3: 24.7%

- **QIDS-SR-16**
  - Lithium: 13.2%
  - T3: 24.7%

Percentage Reduction in MADRS Scores with Buspirone vs. Placebo Augmentation of SSRIs

Low-Dose Combination of Buspirone (15 mg/day) and Melatonin (3 mg qhs), Stimulating Hippocampal Neurogenesis, in MDD

*\(p<.05\) combination vs placebo and buspirone alone.

This information includes a use that has not been approved by the US FDA.

Double-Blind, Placebo-Controlled Study of Testosterone Gel Augmentation in 100 TRD Men Patients

**FIGURE 2.** Mean HDRS scores at each study week and at endpoint (LOCF) in participants receiving testosterone and placebo.

Pope et al, J Clin Psychopharm 2010; 30: 126-134
Double-Blind, Placebo-Controlled Study of Metyrapone Augmentation (500 mg BID) in TRD Patients (n=165)

Eligible patients were aged 18–65 years with TRD (HAMD-17 score of ≥18 and a MGH Treatment-Resistant Depression staging score of 2–10) and taking a single-agent or combination antidepressant treatment that included a serotonergic drug.

Other Augmentation Strategies

- **Inositol (up to 12 g/day)** - recent double-blind study failed to support its use (Nemets B et al. J Neural Transm. 1999;106(7-8):795-8.)

- **DHEA (up to 90 mg/day)** – small, positive double-blind study (Wolkowitz OM et al. Am J Psychiatry. 1999 Apr;156(4):646-9.)

Combination

- **Definition:** The concomitant use of two antidepressants to enhance their therapeutic effect

- **Rationale:**
  - To obtain a different neurochemical effect by combining antidepressants affecting different neurotransmitter systems
  - To combine antidepressants with different mechanisms of action
Combination NE and 5-HT Reuptake Inhibition vs. Either Alone

Trazodone plus SSRIs

Fig. 1. Mean Hamilton Depression Rating Scale (HDRS) score at baseline (W0), 1 week after treatment with trazodone 100 mg/day (W1), and at weeks 3 (W3) and 5 (W5), after randomization of the patients (at W1) to receive trazodone 100 mg/day + placebo (TR + PL), trazodone 100 mg/day + pindolol 7.5 mg/day (TR + PIN), or trazodone 100 mg/day + fluoxetine 20 mg/day (TR + FLUOX).
Conclusions

• Treatment resistance is common in MDD

• Many strategies may be effective approaches for partial and non-responders to antidepressant treatment

• The potential loss of partial benefit from the failed trial may reduce the feasibility of switching strategies

• The presence of significant side effects from the antidepressant itself may reduce the acceptability of dose increase, augmentation and combination strategies
